This has created a wide space for the development of sustainable and renewable energy sources. Biodiesel has attained exceptional contemplation among other biofuels due to the use of renewable and low-cost resources. Selection of suitable catalyst plays a vital role in biodiesel production by a catalytic transesterification reaction. Compared to homogeneous catalysis, heterogeneous catalysis are more preferred as they have high selectivity and stability with increased biodiesel yield. Heterogeneous catalyst has made incredible development in biodiesel production under mild operating conditions and has less impact on the environment. Nanocatalysis are the effective heterogeneous catalyst, which has brought a tremendous revolution in biodiesel production in recent years. Thus, present review provides a comprehensive analysis of the use of heterogeneous catalyst, importance and challenges associated in biodiesel production. © 2020 Elsevier B.V. Though there are a number of techniques available to ascertain a fruit's quality, Hyperspectral imaging techniques are gaining popularity because of their striking features in assessing the quality attributes of the fruits in a simple, continuous, non-invasive and economical way. This survey is focused on uncovering the factual details pertaining to the development and the present state of Hyperspectral Imaging techniques' contribution in assessing the quality of fruits. Most of the research publications considered in this survey focusing on the Hyperspectral Imaging Technique had considered three major internal quality parameters of fruits namely Moisture Content (MC), Total Soluble Solids (TSS) and Firmness. At the end of this survey, a short list of quality literature had been suggested for interested readers to guide and provide them the necessary support to quickly grasp the application of Hyperspectral Imaging Techniques in assessing the quality of fruits.</p>

In this paper, the diseases in the leaves are detected by extracting high quality features of the leaf by Principal Component Analysis. The input image is pre-processed by removing the noise using median filter, extracting the edges using Sobel filter, identifying the direction of the leaf using Gabor filter and segmenting the image by threshold segmentation. Finally, Linear Support Vector Machine classifier identifies the support vectors to identify the disease. Experiments are carried out using the datasets of tomato plant leaves where tomato is cultivated large scale in Coimbatore, India. Powdery mildew and early blight diseases are the most common disease in tomato which is detected and analysed in this work. The results obtained shows that there is an increase in accuracy when compared to other methodologies.</p>
